ACKNOWLEDGMENT

To increase the usefulness of the water quality data, annual compilations since 1958, including this one, have presented preliminary and unadjusted flow data for gaging stations at or near most of the Public Health Service Water Pollution Surveillance System sampling points. Final data may be obtained directly from the agency concerned. Any studies using the provisional flow data herein compiled should verify the data prior to completion of reports on such studies. For making the flow information available for this publication, grateful acknowledgment is made by the Public Health Service to:

The International Boundary and Water Commission,
United States and Mexico

The International Joint Commission, United States and Canada

The U.S. Department of the Interior
Bureau of Reclamation • Geological Survey

The U.S. Department of the Army
Corps of Engineers • Lake Survey

FOREWORD

This is the sixth annual compilation of data from the Public Health Service Water Pollution Surveillance System (formerly the National Water Quality Network). During this year, the System was increased from 122 to 128 stations. In order to provide data in a form more useful for local or regional water pollution control officials and their staffs, the present compilation is published in 11 separate volumes. The surveillance data reported herein reveal additional findings on pesticides and other organic chemicals in surface waters and on trends in radioactivity and other areas.

The Public Health Service gratefully acknowledges the assistance to our Surveillance System of the participating local, State and Federal Government agencies and private industry. The success of this program depends, in a large measure, upon their continued interest and support.

ANALYTICAL AND FLOW DATA INDEX

THE PUBLIC HEALTH SERVICE

Water Pollution Surveillance System

The Public Health Service program for providing fundamental information on the quality of the Nation's waters stems from Public Law 660, approved July 9, 1956, as amended by Public Law 87-88, July 20, 1961. Section 4(c) thereof states: ". . . the Secretary (of Health, Education, and Welfare) shall in cooperation with other Federal, State, and local agencies having related responsibilities, collect and disseminate basic data on chemical, physical, and biological water quality insofar as such data or other information relate to water pollution and the prevention and control thereof."

To fulfill this responsibility, the Public Health Service Water Pollution Surveillance System collects, interprets, and disseminates:

a. Information on changes in water quality at key points in river systems, as such quality may be affected by changes in water use and development.

b. Continuous information on the nature and extent of pollutants affecting water quality.

c. Data which will be useful in the development of comprehensive water resources programs.

d. Data which will assist State, interstate, and other agencies in their water pollution control programs, and in the selection of sites for legitimate water uses.

Some 50 sampling stations were established when the program started, October 1, 1957. By September 30, 1963, the number had grown to 128.

Each sampling location satisfies one or more of the following criteria:

a. Major waterways used for public water supply, propagation of fish and wildlife, recreational purposes, and agricultural, industrial, and other legitimate uses.

b. Interstate, coastal, and international boundary waters.

c. Waters on which activities of the Federal Government may have an impact.

Sampling station sites are fixed only after consultation with local, State, Federal and other agencies having related interests.

Active local participation is important in this operation. It assures maximum development of all information valuable both locally and nationally. Program costs are shared by the Federal Government and State and local agencies, those of the latter through contributions of laboratory and sampling manpower. Specifically, the State and local agencies perform certain of the conventional chemical analyses and collect samples for the newer, more complex examinations. The Public Health Service, in turn, performs the more complex determinations and makes the results available to the participants and to the public. In addition, the consultation, training facilities, and other resources of the Public Health Service are available to the cooperating agencies.

Locations of sampling stations in operation as of September 30, 1963, are shown on page 2. Descriptions of the stations, participating agencies, and other pertinent information are presented with the station data.

Only after careful screening of needs in water resource development was a pattern set for analyses of water samples.
All System samples are examined for:

a. Radioactivity.
   (1) Gross alpha.
   (2) Gross beta.
   (3) Strontium 90.
b. Plankton populations.
c. Coliform organisms.
d. Organic chemicals.
e. Biochemical, chemical, and physical measurements, including biochemical oxygen demand (BOD), dissolved oxygen (DO), chemical oxygen demand (COD), chlorine demand, ammonia nitrogen, hydrogen ion concentration (pH), color turbidity, temperature, alkalinity, hardness, chloride, sulfate, phosphates and total dissolved solids.
f. Sodium, potassium, fluoride and trace elements.

Samples for groups c and e were collected and analyzed weekly. Samples for organic chemicals were collected and analyzed monthly and plankton organism examinations were conducted semimonthly. Water samples for analysis of suspended and dissolved gross alpha and beta radioactivity were submitted weekly. Strontium 90 analyses were made on composites of weekly samples accumulated over 3-month periods. Sodium, potassium, fluoride, and trace metals were also determined on 3-month composites of weekly samples. New parameters which are developed and found significant will be included as the program continues.

Analytical Methods and Reliability of Data

The physical, chemical and biochemical data documented in this publication are the result of efforts of the cooperating agencies. In general, about half of these measurements were contributed by their laboratories. Specifically, all measurements reported for temperature, pH, DO, BOD, COD, chlorine demand and ammonia nitrogen were performed by the participants at the sample collection point. In addition, about 45 of the participating groups regularly perform all or most of the determinations for the remaining parameters included in the data. Whenever possible, analyses for stable constituents not completed by the participants are completed in the central Water Quality laboratories. While individual laboratories make minor modifications to meet local conditions, the methods used in most cases are those published in the 11th edition, starch-iodide titration procedure, and the chemical oxygen demand test is restricted to the use of 0.025 N reagents.

To assure continued reliability in the published data, frequent analysis of reference samples are made by each cooperating laboratory as an integral part of the overall program. Periodically a synthetic standard sample is provided to each participant for reference analysis. The reported results are reviewed. Any significant errors are called to the attention of the reporting laboratory and, after the cause of the errors has been determined, the previously submitted data are either corrected or discarded. From these findings, the analyses reported in this compilation are believed to be accurate to ± 10 percent of the reported values.

The analytical methods used by the Public Health Service labora-

Water Pollution Parameters

In the assessment of water pollution, all of the legitimate purposes for which raw waters can be used, and which may be affected by pollution, must be considered. These may range from the minimum requirements for navigation to the ultimate in water quality demanded for certain industrial processing. Standards differ considerably, therefore, according to water use.

For domestic use, water must be free of disease organisms, clear, colorless, taste- and odor-free, and have a relatively low dissolved mineral content. Agricultural water is judged primarily on its mineral content, especially with respect to the ratio of sodium to other cations, and the presence of boron. Water for fish propogation and recreational purposes must be relatively free from domestic and industrial pollution and must be able to sustain an active flora of the smaller aquatic organisms on which fish and wildlife feed. Industrial water quality demands run the gamut from the complete absence of minerals to a requirement of low temperature, the critical factor in water used for cooling. The effects of radioactive materials on these uses have not yet been fully appraised.

The various laboratory examinations made as part of this program are discussed below.

Radioactivity

Radioactivity, long recognized as a water contaminant from natural sources, has continued to grow in importance and health significance with the development of nuclear energy for both military and peaceful uses. Consequently, levels must be measured continually as new sources are established.

Gross alpha and beta measurements are made on both suspended and dissolved solids in the raw surface water samples. The total radioactivity in the dissolved solids provides a rough measure of the levels which may be found in a treated water, where water treatment removes substantially all of the suspended matter.

Beta activity levels generally reflect the variable contamination resulting from fallout and discharges from nuclear energy installations, institutions utilizing radioactive materials, and other manmade sources. The trend of gross beta radioactivity in samples received from 47 of the Public Health Service Water Pollution Surveillance System stations operating since 1957 is presented in Figure 1. During the first three quarters of the 1962 water year, renewed weapons testing resulted in a rise in gross beta radioactivity in surface waters of the United States. During the sec-

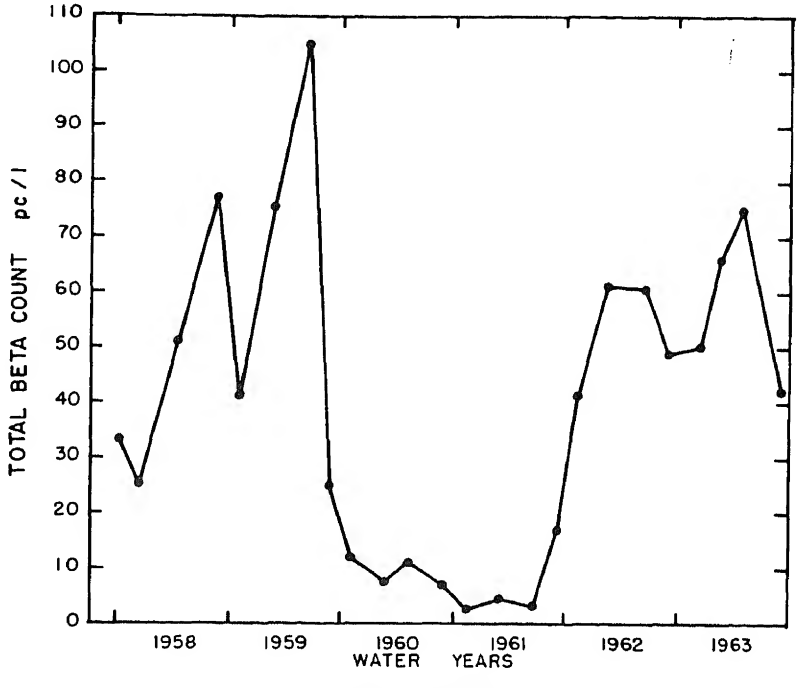

FIGURE 1. GROSS BETA RADIOACTIVITY IN THE SURFACE WATERS OF THE UNITED STATES.

ond and third quarter of water year 1963, the national average activity reached a maximum of 75 pico curies per liter and then decreased. Beta levels have remained well below the Public Health Service Drinking Water Standard of 1,000 pc/l or $\mu\mu$c/l (26).

Alpha levels reflect largely the activity added by uranium and thorium daughters. The waters of the United States can be characterized in a general way with respect to gross alpha radioactivity content. Gross alpha levels average less than 1 pc/l in east coast, Appalachian, Great Lakes, and Pacific Northwest States. On the Colorado Plateau, and along the eastern slope of the Rocky Mountains, natural radioactivity, principally from mineral deposits, results in average concentrations of about 20 pc/l.

Gross levels are most informative in ascertaining long-term trends or changes in water quality. By themselves, however, they are of limited value in assessing radiation exposure. Where gross results are consistently over the maximum permissible concentrations for mixed fission products, the identity of the specific radionuclides involved must be established.

Because of its significance in the environment, the concentration of strontium 90 in the total solids is also reported. In water year 1963, strontium 90 levels ranged from 0.4 to 11.3 pc/l. The national average reached a high of 3.8 pc/l during the fourth quarter (July, August, September 1963). Highest levels were in the north-central area of the coterminous United States where the average was approximately 6 pc/l for this quarter. All averages were less than the limit (10 pc/l) specified in the Public Health Service Drinking Water Standards (26). The levels of strontium 90 activity in waters of the United States since the first quarter of the 1959 calendar year are presented graphically in figure 2.

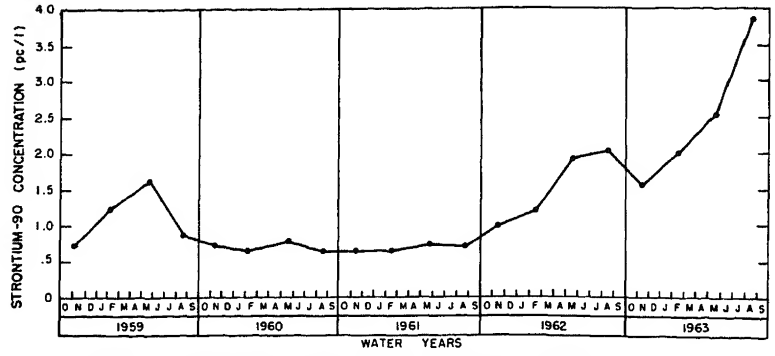

FIGURE 2. STRONTIUM-90 IN SURFACE WATER OF THE UNITED STATES.

Plankton Populations

Geographical distribution of algae and other planktonic organisms are influenced by geologic and climatic factors, and result in distinctive plankton populations in different areas. Within each region, population changes are directly related to temperature, and the nature and concentration of organic and mineral substances which enter the aquatic environment. These substances may come from domestic sewage, industrial wastes, runoff from agricultural lands, irrigation discharges, or native rocks and soils. They may be basic nutrients, highly toxic, or metabolically inert. Planktonic organisms differ greatly in their sensitivity to the nutrient and toxic substances which are present. Some thrive only in water which is relatively free of nutrients while others multiply rapidly in water which has been greatly enriched. Large numbers of tolerant algae usually develop in waters containing abundant supplies of inorganic nitrogen and phosphorus resulting from the mineralization of domestic sewage. These nuisance populations may clog filters in municipal water plants, and produce objectional tastes and odors.

On the other hand, plankton populations may be eradicated by the introduction of toxic organic or mineral wastes. This is not desirable because some plankton organisms play essential roles in providing food and oxygen for higher forms of aquatic life, and in cleansing polluted waters.

Beginning at low nutrient levels, progressive enrichment of waters results in an increase in the variety and abundance of the plankton. However, as higher levels of enrichment are attained, the increase in total numbers of organisms is accompanied by a decrease in the number of kinds of organisms. This change is typical in populations which have been subjected to the wide spectrum of substances being introduced into

surface water in ever increasing amounts. Plankton counts, which provide information concerning the variety and abundance of organisms, are useful in detecting changes in the concentration of organic and mineral substances which enter water supplies.

METHODS OF ANALYSIS

Plankton samples are collected semimonthly at each station. A sample consists of 3 liters of raw water taken directly from the stream or from a treatment plant intake. Preservation is effected at the time of collection by the use of 30 ppm merthiolate.

Three types of analyses are performed:

1. Rotifers, crustacea, and other micro invertebrates are removed from a 1-liter aliquot of the sample by settling 24 hours. The sediment is placed in a special slide, 80 x 50 x 2 mm., and the organisms are enumerated under a compound microscope at 100× magnification. The counts are reported as organisms per liter.

2. A "total live algae" count is obtained from 1 milliliter of the sample by scanning two 50-mm. strips on a Sedgwick-Rafter slide using 200× magnification and a Whipple micrometer disc. An appropriate correction factor is used to convert the counts to units per milliliter. Each single cell or natural aggregate of cells (colony) occupying up to 300 square microns (μ^2) is counted as 1 unit. Large colonies are enumerated according to a modified areal-unit method in which aggregates occupying 300–1,000μ^2 are counted as 2 units, those occupying 1,000–2,500μ^2 as 3 units, those 2500–5000μ^2 as 4 units, and those over 5,000μ^2 as 5 units. About 95 percent of cell aggregates fall into size 1 or 2.

3. Identification and proportional census of diatom species are done from sediment obtained by settling 1 liter of the sample 48 hours. A small aliquot of the sediment is placed on a No. 1 coverglass and dried on a warming table. The sediment is ashed on the coverglass by heating on a hotplate, and permanent slides are made with hyrax mounting medium. Counts are made with 90× apochromatic oil immersion objectives and 10× oculars containing a Whipple micrometer disc. Random strip counts are made until the total number of units reaches 200 to 300. The same areal units are used as described for Sedgwick-Rafter counting.

Organic Chemicals

The Nation's water resources continue to receive increasing quantities of organic contaminants. Since 1940 the chemical industry, particularly in the manufacture of synthetic and petrochemicals, has experienced an enormous expansion that shows every sign of continuing. Each year millions of pounds of synthetic detergents, insecticides, herbicides, and similar domestic products find their way into our streams from household sewers, industrial waste discharges, and land runoff.

Effective and economical treatment methods for most of the complex organic materials remain to be developed. Even where treatment exists, residues may remain in sufficient quantity to cause water damage. These stable residues persist through sewage treatment, biological and chemical action of the stream, and water treatment processes, and finally reach the consumer in drinking water.

The presence of some of these materials, even at concentrations considerably less than 1 part per million, may impair water quality, most noticably in production of tastes and odors. Fishflesh tainting, also quickly noticed by the consumer, is another damage. Effects on water treatment, many of which are ill-defined at present, and impairment of water quality for industrial uses are being reported with increasing frequency. Essentially nothing is known of the possible immediate or long-term effects of these materials on human health. Such information is urgently needed.

The usual sanitary analyses are not effective in measuring these newer organic contaminants. Yet it is essential to know something of their concentrations and character. A method known as the "Carbon Adsorption Technique," developed by the Public Health Service, permits the concentration of these organic compounds from a large volume of water. Elution of the adsorbed materials with organic solvents, followed by chemical separation and testing, provides useful information concerning organic pollution and for assaying river systems for these substances.

Following continuous flow of about 5,000 gallons of water through the carbon adsorption column over a 7- to 10-day period at 0.5 gpm, material on the carbon adsorption column is extracted with two solvents, chloroform and alcohol. The residues are weighed. The concentration of these materials in the water sampled is then computed. See Explanation of Analytical Data, page 21.

CHLOROFORM EXTRACTS

The organic residue recovered from the carbon adsorption column by chloroform is very complex. It is desirable to separate the crude extract into certain broad chemical classes, and this can be done on the basis of solubility differences. The various classes or groups and their general significance are discussed briefly below.

Ether Insolubles

This group is usually a brown, humuslike powder, apparently composed to a large extent of carboxylic acids, ketones, and alcohols of complicated structure. Origin of the group, which is an indicator of "old" pollution, is believed to be partially oxidized sewage and industrial wastes. For example, the Ohio River at Cincinnati has been exposed to much industrial and sewage pollution, and hence large amounts of ether insoluble materials are found. Streams with little or no pollution history have little or no ether insolubles. Chloroform extracts contain from 0 to 30 percent of ether insoluble material.

Water Solubles

These substances are largely acidic and undistillable at moderate temperatures, but their solubility in ether indicates that the molecules are smaller and probably simpler than the ether-solubles. On the other hand, their water solubility practically requires the presence of several functional groups, such as hydroxy-acid, keto-acid, and keto-alcohol. Such compounds probably originate from partial oxidation of hydrocarbons or they may be natural substances. They have very little odor. These materials usually make up 10 to 20 percent of the total extract.

Weak Acids

This group is characterized by being removed from ether solution with sodium hydroxide but not with sodium bicarbonate. Phenols are the best known weak acids, and if present in the water, appear in this group. Other weakly acidic compounds include certain enols, imides, sulfonamides, and some sulfur compounds. This group of materials also occurs in nature. The weak acids are odorous, and commonly constitute 5 to 20 percent of the chloroform extract.

Strong Acids

These acids are usually carboxylic acids such as acetic, benzoic, salicylic or butyric. Although classified as strong in reference to carbonic acid, they are actually weak when compared with a mineral acid, such as sulfuric. Many of the compounds are used industrially, but may also be produced by natural processes, such as fermentation. Some of the materials are highly odorous. This fraction makes up from 5 to 20 percent of the total. The significance of the strong acids can be interpreted only in the light of stream pollution conditions.

Bases

These compounds are organic amines. Such materials as aniline and pyridine are amines of commerce. Lower amines may occur as a result of decomposition. Although odorous, the low concentrations found are not likely to cause objectionable conditions. However, in the case of specific amine-containing wastes the compounds can be of considerable significance. Generally, only 1 or 2 percent of the total extract is made up of the bases.

Neutrals

This group frequently constitutes the major portion of the chloroform extract. Neither basic nor acidic, the materials are less reactive and tend to persist in streams longer than many other types. Hydrocarbons, aldehydes, ketones, esters, and ethers are examples of neutral materials. The group lends itself to further fractionation by means of chromatographic separation into aliphatic, aromatic, and oxygenated subgroups:

Aliphatics: This portion represents petroleum type hydrocarbons in a considerable state of purity, and is usually made up of mineral oil type of material. The percentage of aliphatics present yields important information about the possible source of pollution, since petroleum is the most likely source.

Aromatics: These are principally the coal tar hydrocarbons such as benzene, toluene, and a host of others, and their presence in any significant amount is a reliable indication of industrial pollution. Further, the materials can frequently be identified by infrared spectrophotometry. Some aromatic compounds which have been found in our rivers—and in our drinking water—include DDT, aldrin, endrin, dieldrin, phyenyl ether, orthonitrochlorobenzene, pyridine, phenol, and others. The materials are highly odorous, and may also be toxic. Their appearance in any quantity as pollutants should receive careful evaluation.

Oxygenated compounds (Oxys): These are the neutral compounds containing oxygen, such as aldehydes, ketones, and esters. They may have originated by direct discharge or may represent oxidation products from both natural and industrial materials. They help to indicate the "age" of the pollution, since pollution exposed to oxidation forces for a long time would be expected to contain large amounts of oxys. The oxy materials are odorous.

Losses

Manipulative losses inherent in this type of separation may amount to 10 to 15 percent. Losses greater than this may indicate that volatile components were lost from the sample. Such volatiles may have significance as pollutants.

ALCOHOL EXTRACTS

The alcohol extractables generally consist of materials more polar than the chloroform extractables. They often contain synthetic detergents, carboxylic acids and humic materials which may originate naturally or from oxidized products of domestic and industrial wastes. These classes of substances are not quantitatively recovered by the alcohol extraction. For example, this extraction recovers only 20 to 30 percent of the synthetic detergents present. On waters of mixed industrial and domestic pollution, the chloroform and alcohol extractables may be about equal. On some streams where the industrial pollution is rather low and much natural pollution or sewage is present, the alcohol extractables may exceed the chloroform extractables by a factor of 4 to 6.

The alcohol extract is usually only partially soluble in water and most ordinary solvents. Very little further chemical separation of this material is currently practical. However, tests have revealed that synthetic detergents may make up 1 to 12 percent of the alcohol extract.

OTHER TESTS

Infrared spectra are routinely run on the total chloroform and alcohol extracts as well as the neutral, aliphatic, aromatic and oxygenated groups which are usually the most significant. Spectra of other groups are obtained when there is an indication that they may be significant. These spectra reveal something of the chemical structure of the materials, indicate differences and in certain instances provide a definite identification. In the case of the alcohol extracts, the infrared spectra will indicate the presence of synthetic detergents if the materials constitute a significant portion.

Thin layer chromatography has been applied successfully to the resolution of the aromatic and basic fractions of CCE. Gas chromatographic equipment with flame ionization, electron-capture and microcoulometric detectors have also been used freely in the identification of specific substances.

COMPOSITE ANALYSIS

Samples from certain locations have been selected for analysis on a quarterly composite basis. Stations that have collected at least 12 samples in a nearly consecutive manner and averaged 100 ppb. or less of chloroform extractables are selected for such analysis when certain other conditions are met. However, samples falling in this category are analyzed individually when the recovery of the chloroform extract is exceptionally high and/or it is unusual in its infrared spectrum or some other physical characteristic.

736-491 O—64——2

SPECIFIC IDENTIFICATIONS

Information about specific organic substances which were identified in carbon adsorption samples is given on the second page of the group associated with each station. The increased number of pesticide and other specific compounds identified, as compared to previous years, is partly associated with greater sensitivity in analytical methodology and may be partly a reflection of the increasing usage of these substances in the total environment.

Chemical, Physical, and Bacteriological Examinations

The various biochemical, chemical, physical, and bacteriological examinations generally performed by the participating laboratories are discussed below.

AMMONIA NITROGEN AND CHLORINE DEMAND

The cost of water treatment for domestic use is affected by the consumption of chlorine, with ammonia nitrogen being responsible for a large portion of the chlorine demand. The greater this demand, the more expensive is the treatment. The ammonia may originate from unstabilized domestic pollution, from industrial waste discharges, from run-off containing fertilizers used in farming operations or from all three. The presence of measurable quantities of nitrogen compounds, not necessarily ammonia, is also an indication of the fertility of the stream toward both macro- and micro-biological forms.

COLOR

Color in domestic water supplies is undesirable. Its removal in the water treatment process, whether it be from natural or industrial sources, may require large doses of chemicals and be expensive.

DISSOLVED OXYGEN, BIOCHEMICAL AND CHEMICAL OXYGEN DEMANDS

Biochemical processes, in which aquatic organisms attack and stabilize the organic matter present, require dissolved oxygen. If unstable oxidizable organic matter is present in excess, the organisms will multiply rapidly, consuming the oxygen present in the water, and bring about a foul, septic stream condition. The dissolved oxygen level thus serves to indicate the biochemical activity of the stream. High activity, resulting in low dissolved oxygen levels, will drive out game fish in favor of scavengers. Very low or zero oxygen levels will kill all fish and aquatic organisms dependent on dissolved oxygen for life. Temperature and reaeration rates also affect dissolved oxygen levels.

The 5-day biochemical oxygen demand (BOD) indicates the degree of unstabilized organic pollution from either domestic or industrial sources, to which the stream is being subjected. A significant demand will affect the fish and macroorganism population, and waters carrying a high BOD seldom contain game fish. On the other hand, game fish will thrive in streams in which the oxygen demand has been stabilized, as this condition is usually favorable for the growth of organisms on which fish feed.

The chemical oxygen demand analysis serves to support the findings of the biochemical oxygen demand test. It too may indicate to what extent the waste load of the stream has been stabilized, or it may indicate the presence of organic and inorganic pollution which is not readily oxidized by biological processes. Because the chemical oxygen demand can be determined quickly in comparison to the biochemical oxygen demand, the establishment of a correlation between the two parameters serves to reduce the number of the latter determinations required. The chemical demand results are nearly always higher than the biochemical demand.

TEMPERATURE

Temperature is particularly important to conservation and industry. A few degrees elevation in temperature due to cooling water discharges may seriously limit the capacity of a stream to support fish life. Also, high water temperatures increase the cost of cooling water for

industrial operations. Cooling towers and other equipment for handling cooling water must be engineered to the temperature levels normally encountered.

MINERAL CONSTITUENTS

These determinations include alkalinity, hydrogen-ion concentrations (pH), hardness, chlorides, sulfates, and total dissolved solids. The pH indicates whether water is acidic or alkaline, corrosive or passive. Alkalinity is a measure of the neutralization reserve present, or the extent to which the water can resist a change from an alkaline to an acid condition upon addition of acidic chemicals. This information is important to the water treatment plant operator and to many other water users.

Hardness is not only a measure of the soap consuming property, but is also of importance in the treatment of boiler waters, where removal of hardness is one of the most important functions. Chloride, sulfate, and total dissolved solids add further information on the gross dissolved mineral content carried by the stream. These are of great importance when considering the taste or palatability of water. They are also important when the water is being demineralized for specific industrial processes, since the cost of demineralization is a direct function of the dissolved solids content of the water. In addition, waters of high saline content are less desirable and may at times even be unfit for municipal, irrigation, and other uses.

TURBIDITY

Turbidity of water is due to the suspension of clay, silt, finely divided organic matter, microscopic organisms, and other similar materials. Its presence is of particular importance in water treatment processes and in the propagation of fish and other aquatic life.

COLIFORM ORGANISMS

Information about fecal pollution is essential to water quality measurements. Data on coliform bacteria, used as indicators of pollution, help to point up the trends in the effectiveness of treatment of domestic waste discharges.

The delayed-incubation membrane filter technique is used for the coliform examination, instead of the fermentation tube (MPN) method. The latter necessitates transport of water samples to the Water Quality Section laboratory for examination, with a time lapse between collection and examination that can significantly change their microbial content. Also, some of the many other bacteria present in raw water might overgrow or otherwise inhibit the demonstration of the coliform organisms. In the delayed-incubation membrane filter procedure, the bacteria are filtered out from the fluid samples immediately after collection and the filters sent to the Water Quality Section laboratory on a preservative medium. In the laboratory the membrane filters carrying the bacteria are transferred to a medium selective for coliform organisms, then incubated and counted. The resulting counts approach very closely the actual numbers of coliform bacteria present in the water samples at the time of collection.

Unusual populations of coliform bacteria may mean increased pollution and ensuing loss of water quality. The Public Health Service Water Pollution Surveillance System studies and reports the trends in sewage pollution on streams as indicated by the trends of coliform counts.

Trace Elements and Other Determinations

This year's trace element data differ somewhat from data reported in previous compilations in that the manner of obtaining the data has been modified and the program of elements measured altered. The trace metals measurements are now obtained from a 3.4 meter direct reading spectrograph. Tin, antimony, and bismuth have been discontinued; arsenic, boron, phosphorus, aluminum, and strontium have been added. Increased sensitivity for several elements has been attained, especially zinc, manganese, and beryllium, resulting in fewer indeterminate values.

Twice during the year, 3-month composites of the weekly samples were prepared and subjected to analysis. Examinations covered those elements included in the Public Health Service Drinking Water Standards (26), and other metals considered to have possible physiological or

toxicological significance. The ultimate goal of this phase of the program is to provide background data on all elements which may be found in water and which may be of significance in water quality management.

In carrying out the spectrographic examination, the sample is first passed through a membrane filter, .045 micron pore size, to remove all suspended matter. An aliquot of sample is then acidified with redistilled nitric acid and evaporated to a concentration containing 100 mg. of dissolved solids in 5.0 ml. A portion of the prepared sample is placed in a porcelain boat and sparked using a rotating disc, with concentrations of the 19 programed elements measured on the direct reader (*12*).

Waters of low dissolved solids content can be concentrated to a greater degree than those having a high dissolved solids content, thus accounting for the variable sensitivity shown in the tabulations. Values followed by an asterisk (*) show the limits of sensitivity at which the test was performed and indicate that the ion being measured was not detected at that level.

It is known that trace concentrations of some ions are subject to precipitation and adsorption on container surfaces during storage. This applies particularly to iron and manganese which are subject to oxidation. Hence, all the values reported by the spectrographic method represent the quantity of metal in solution at the time of analysis to within about 10 percent.

The measurement of sodium and potassium is performed using a flame procedure. Fluoride is determined with the SPADNS reagent using the method described by Bellack and Schouboe (*3*). Boron, previously measured by the curcumin procedure, is now reported from the spectrograph. Measurement of selenium has been eliminated due to the general absence of this element from the samples examined.

The concentrations of surface active agents, reported as alkyl benzene sulfonate (ABS), in the Nation's surface waters is reported for the first time on a number of selected stations. As the capability of determining this pollutant increases, efforts will be made to include all sampling points in the Surveillance System. The data presented here were obtained using a modification of the Standard Methods methylene blue procedure on an automatic analyzer.

The Benthos

Animals and plants that live in or on the bottom substrata of lakes and streams are known as the benthos. This biological community includes such common animals as immature insects, worms, clams, snails, and crustacea. The benthic populations found on a stream bottom are largely determined by the type of substrate. Bottoms consisting of soft silty sediments are normally inhabited by animals that are able to burrow into the sediments and feed on organic detritus in the sediments. These include worms, clams, and certain insect larvae. The number of species is usually small in these habitats. Shallow streams with shoals, rapids, and riffles have more available niches for animals to occupy and the normal benthic fauna usually includes a large variety of organisms.

The benthic populations provide a basic indicator of general water quality. Whereas the plankton organisms move downstream with the current, and fish are able to migrate considerable distances, the benthos is a population relatively fixed on the bottom and the animals are subject to the water flowing over them. The benthic populations will therefore be influenced by the quality of the water.

The animals that make up the benthos have various life cycles. Insects may exist as aquatic larvae living in the bottom for as long as 2 years. They then emerge as adults and mate. The female deposits fertilized eggs into the stream. Some of the class produce young which attach themselves to fish. Some of the worms reproduce asexually. An analysis of the age structure of certain forms in the benthos may provide information on past conditions of the water.

Under conditions of good water quality the benthos should include a variety of species with no one species being present in excessive numbers. If the water should become degraded, certain species in the population, intolerant of the changed environment, will die out; and as the water quality deteriorates, increased numbers of species in the benthos will be eliminated. The one or more species that survive may be able to develop very large populations. Toxic materials in the water or deposited on the bottom may effectively eliminate all bottom life.

At each station where bottom samples are taken an attempt is made to find areas of suitable substrate. From these areas, where pos-

sible, a series of at least six quantitative samples is taken by means of suitable dredges or samplers. In riffles the Surber squarefoot sampler is used. In deep rivers the Ekman or Peterson dredge is used (see Standard Methods, for the Examination of Water and Wastewater, 11th edition, pp. 572–582) (22). A general qualitative collection of invertebrate life is usually made at all stations.

The bottom materials are screened in the field using a screen with 28 meshes to the inch. The concentrated sample is preserved in alcohol and returned to the laboratory.

In the laboratory the sample is transferred to pans and the macroscopic organisms are separated from the sediment and detritus. The animals are then identified as near to species as possible, enumerated, and weighed. Specimens are preserved and retained for future reference.

During this year benthos data were gathered for stations in the Ohio and Tennessee River basins only and are presented with the descriptive material for the appropriate stations. A supplemental analysis of these data will be published separately.

Fish Populations

Fish are a biological end product of the aquatic environment. They are an important source of food, and sport fishing is one of our leading forms of recreation. The maintenance of fish life has been recognized by the Congress, and by States which have protective pollution control legislation, as an important and legitimate use of our Nation's waterways. In other words, in measuring fish populations at Surveillance System stations, we are not measuring a parameter that affects a water use as in the case of other measurements presented in this compilation, but rather a unique parameter that is in itself considered a beneficial water use.

The water quality requirements and tolerance of aquatic life to different types of contaminants vary tremendously. It is this variability in response which makes living aquatic organisms usable indicators of environmental disturbance. Fish require water relatively high in dissolved oxygen, and are intolerant of many chemical and physical contaminants resulting from agricultural, industrial and mining practices. However, the tolerance of different species varies, and man-induced changes of the environment often affect one species more than another, producing imbalanced populations which quite often favor the species less desirable economically.

Moderate amounts of putrescible wastes may enrich the habitat, resulting in great increases in standing crops of fish present. However, under such conditions, the more tolerant and adaptable species may comprise a disproportionate share of the total population, and very sensitive species may be eliminated altogether. The effect of toxic wastes may vary from complete elimination of populations to a reduction in reproductive capacity, growth and resistance to disease and parasitism.

Fish kills are a spectacular and obvious indication that an abrupt change has taken place in the environment. However, because of high mobility resulting in rapid recruitment, the fish population in a river or stream may return to normal levels within a very short time after a kill.

Chronic pollution, to which the fish population must adjust over a period of time, will be reflected in the kinds and relative abundance of the fish species present. In addition to the species composition, the condition of the fish, their growth, reproductive success and certainly their palatability are factors of considerable importance in evaluating the suitability of a body of water for supporting usable stocks of fish.

During the current water year, data on fish populations were gathered for some stations in the Ohio and Tennessee River basins only, and are presented in tables in volume 5 for the appropriate stations.

Fish samples at these stations were collected primarily with rotenone and with an electrofishing device. Five percent emulsified rotenone was applied at suitable sites, where an area of 1 to 3 acres could be blocked off with nets during the rotenoning operation. Such sites were usually in the form of small coves along the shoreline, the mouths of small tributaries, or behind the partial enclosure created by navigational lock walls. An electrical shocking device was used along the shoreline both during the day and at night. In a few cases, samples were also collected with trammel nets and with short, 25-foot haul seines. Sampling with nets and seines was limited because of the paucity of habitat in large rivers which is suitable for using these types of gear.

With each method used sufficient sampling was done to collect as many species present as possible, and to obtain a measure of the relative abundance and size distribution of the various species. Every type of fishing gear is somewhat selective, and the data obtained may not be representative of the actual population composition present in the river at the time of sampling. However, the data obtained by a given method are quantitatively comparable and may be used to evaluate changes in the population composition resulting from natural and man-induced changes in the habitat. Comparisons should be based on samples collected with the same gear, during the same season of the year, and under similar conditions of stream flow and water temperature. These data will be particularly useful in determining the impact of changes in water quality on the fish populations of the Nation's rivers over long periods of time.

For convenience of comparison, the fish in the tables are grouped into six major categories based on food habits and methods of feeding:

I. Large, sight feeding carnivores that feed on other fish. This group includes most game species.

II. Species that feed primarily on insects. This group provides important forage for species in group I.

III. Species that feed primarily on plankton and algae. These also provide important forage for group I species.

IV. Species that feed primarily on mollusks.

V. Omnivores that feed indiscriminately on plant and animal matter from the bottom.

VI. Scavengers that take any available food. Some of the species in this group may sometimes act as predators. The group also includes many important food fish, and species that are tolerant of degraded conditions.

Because foods and feeding habits vary with size, age, and availability of food, there may be considerable overlap between groups. The species listed were grouped according to available literature regarding the main foods of adult specimens of each species.

In the field the total length of the fish was routinely measured to the nearest inch class on a one-half inch interval. Thus a fish in the 5-inch class would measure from 4.5 inches to slightly under 5.5 inches. If the end of the tail touched the dividing line between two length classes, the fish was included in the higher classification. The percent total number and weight are carried to the nearest one-tenth of 1 percent in the tables. The one-tenth of 1 percent was arbitrarily selected for purposes of tabulation, and does not imply such a high level of sampling accuracy.

The fish are listed by common names in the tables according to American Fisheries Society Special Publication No. 2 (1960), A List of the Common and Scientific Names of Fishes From the United States and Canada, Second edition (*1*).

Stream Flow

Stream flow data have a most important role in the utilization of water quality parameters such as are included in this report. For this reason, average daily flow records are reported for most of the sampling stations in the System.

All flow data included in this compilation are *provisional* data furnished by the agencies credited, and are subject to revision by such agencies prior to any final publication. With the exceptions mentioned, the flows are given as furnished to the Public Health Service.

The data were generally furnished in units of cubic feet per second. In general only the first three digits were considered significant. Because of machine limitations the data are reported here in thousand cubic feet per second. Even though three zeros may appear after the decimal, no artificial accuracy of measurement is implied. Only the first three digits should be considered significant. There are two exceptions:

(1) When the flow was over 1 million cubic feet per second, the first four digits are reported, and (2) at times when the Rio Grande flows were extremely low, the data were reported to tenths of a cubic foot per second. These figures are published showing 4 decimal places.

Flow data for sampling stations on the rivers of the Great Lakes system are reported as the monthly mean flow, as computed by the U.S. Lake Survey. In certain other rivers, flow data were computed by the Public Health Service from information supplied by the gaging agency. The methods of computations are shown as footnotes to the data for the applicable stations.

Explanation of Analytical Data

RADIOACTIVITY DETERMINATIONS

In evaluating radioactivity data it should be noted that the reported errors represent counting errors only and the reported values are subject to other errors commonly associated with gross radioactivity analysis. (See Reference 22.)

A dash (—) in the count column signifies that no determination was made. An asterisk (*) following date of sample indicates that determinations are for composites of two or more samples taken on and before the date shown.

Strontium 90 determinations are reported in micro-microcuries per liter as measured from total solids in the sample composited for the quarter. A dash (—) indicates that no determination was made in that period.

PLANKTON POPULATION

Plankton data are reported on two pages. The first page lists the population size of various groups of algae. A coded number shows the ten most abundant genera of algae and their count level. Code numbers used are identified on page 18. Blank spaces on the data sheets signify that counts of other genera were below a level of 150 per ml. The second page of plankton data lists the four dominant diatom species and their occurrence as a percent of the total diatom population. The percent of occurrence of all other diatom species is shown in the next column. Identification codes of species are given on page 19.

The detectable numbers per ml. of fungi, sheathed bacteria and protozoa are shown in the next two columns. The rotifer and crustacea totals per liter are listed together with the genera where these occurred at a count level of five or more per liter for rotifers and three or more per liter for crustacea. Nematode and miscellaneous animal form counts per liter appear in the last two columns.

A dash (—) indicates that no analysis was made. A zero count of each group is indicated by "0". Blank spaces under abundance and dominance columns indicate that the populations were too few to be included or were absent. Coding for abundant genera of rotifer and crustacea population levels are presented on page 20.

Identification Codes of Algae Genera and Count Levels of Most Abundant Genera

KEY TO COUNT LEVEL (per ml.)

1 150 to 300
2 301 to 600
3 601 to 1,200
4 1,201 to 2,400
5 2,401 to 4,800
6 4,801 to 9,600
7 9,601 to 19,200
8 19,201 to 38,400
9 38,401 and over

ORGANIC CHEMICALS

Although units of concentration may be assigned to the values reported herein (µg/l or parts per billion), it is essential that the user of these data consider additional associated information. Introspective examination of the data reported herein has indicated that comparison of concentration values obtained from samples of similar gallonage are more valid than samples of widely differing gallonage. In addition, recent experimental researches have shown that lower flow rates and lower sample volumes than those employed (5,000 gallons at 0.5 gpm) are substantially more efficient and should produce relatively higher concentration values with this method. The first in a series of changes designed to increase sampling efficiency is already underway at Water Pollution Surveillance System stations.

Concentration values reported for specific substances are calculated from quantitative gas chromatographic analysis of the aromatic fractions of CCE. In light of an unknown efficiency of carbon adsorption sampling for these compounds, the reported values represent minima, the actual values being equal to or greater than the reported values.

Zeros when reported have been entered. A dash indicates that the respective results were not reported. An asterisk in the column showing end of sample date indicates that the determinations are for composited samples taken on and before the date shown. The extent of compositing can be determined by examining the gallons filtered, which is the sum of the applicable individual samples immediately above it.

CHEMICAL, PHYSICAL AND BACTERIOLOGICAL ANALYSES

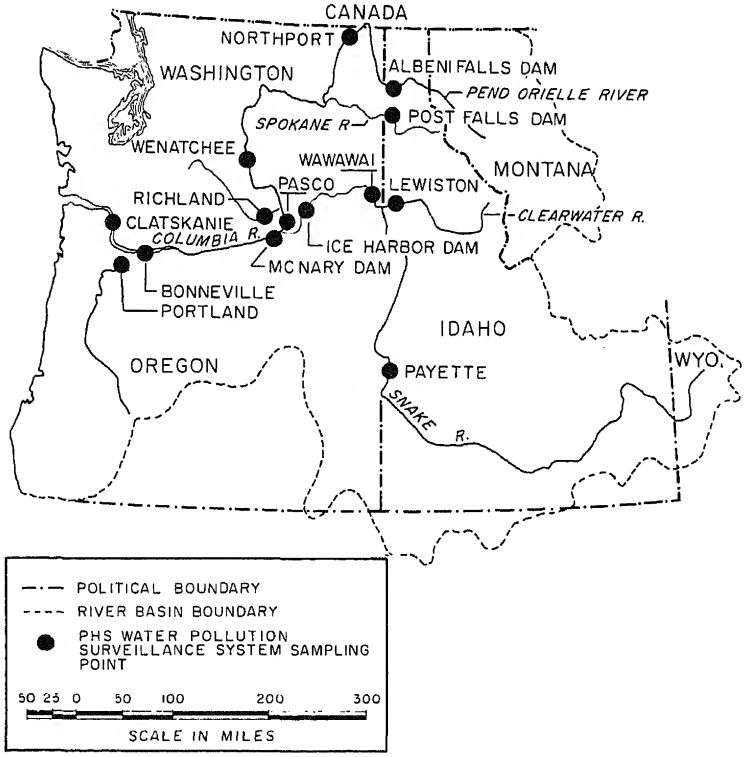
The data entered in each column are as reported. Concentrations of alkalinity and hardness are reported in milligrams per liter as $CaCO_3$. A dash signifies that the particular test was not performed. Zeroes when meaningful have been entered. An asterisk preceding a number should be read as "less than" the number following it.

TRACE ELEMENTS AND OTHER DETERMINATIONS

For a discussion of the sensitivity limits of the determinations performed with spectrographic methods, see page 11.

BASIN 13

PACIFIC NORTHWEST



The Pacific Northwest Basin includes the Columbia River system and the small Pacific Coast drainage basins along the western flanks of the Cascade and Coast Ranges in Oregon and Washington. At present, only the Columbia Basin is included within the Public Health Service Water Pollution Surveillance System.

The drainage basin totals about 259,000 square miles, of which 220,000 lie in the United States, and embraces most of Washington and Oregon, nearly all of Idaho, western Montana, and small portions of Wyoming, Utah, and Nevada.

The *Columbia River* originates in Columbia Lake, in south eastern British Columbia, Canada. It flows 190 miles northwest, thence generally south for about 270 miles to the international boundary. The river then continues for about 750 miles to its mouth, where it enters the Pacific Ocean. The fall from source to tidewater is about 2,700 feet. Many of the tributaries, however, have even greater elevation drops between source and mouth, varying in some instances from 3,000 to 6,000 feet.

The principal tributary is the Snake River, draining an area covering approximately the southeastern half of the United States portion of the basin. Other major tributaries include the Pend Oreille, Spokane, Yakima, and Willamette Rivers. Numerous smaller tributaries also enter the Columbia River throughout its length.

The Cascade Mountain Range lies a short distance inland from the Pacific Coast. Two hundred to 300 miles east of the Cascades is the main range of the northern Rocky Mountains. Ninety-one percent of the land area of the Columbia River Basin, accounting for 75 percent of the runoff, lies in between.

The intervening plateau includes several low mountain ranges and rolling hills, with very steep and precipitous canyons in many places. Much of this area is composed of enormous sheets of horizontal lava flows, covered with surface materials suitable for a variety of agricultural purposes. Nearly all of the interior lands suitable for cultivation are semiarid or near-deserts.

The lower, drier mountain slopes and the dry, interior plateaus are covered by sagebrush and other desert vegetation. The surrounding humid mountains are covered with forests of varying types and

densities, and average precipitation varies from about 40 inches annually in the valleys to 100 inches or more in the mountain areas. Temperatures vary from about 10° to 100° F. along the coast and from minus 50° to plus 120° F. in the inland areas.

Willamette River—This river rises in southwest Oregon and flows northward 300 miles to its confluence with the Columbia River at Portland. It is navigable to Eugene, 178 miles upstream. The Willamette drains the most heavily populated part of Oregon. Agriculture, food processing, and lumbering operations are the principal economic activities.

Snake River—This stream is the chief tributary to the Columbia River. It rises in Yellowstone National Park and flows for about 1,000 miles before joining the Columbia near Pasco, Wash. This stream has cut a canyon which reaches a depth of 5,500 feet. The major population centers of Idaho are located along this stream and both private and Federal irrigation projects are active.

Yakima River—This stream rises on the east slope of the Cascade Range and flows 203 miles to the Columbia. Extensive use is made of this stream for irrigation and hydroelectric power.

Spokane River—This river originates below Coeur d'Alene Lake in western Idaho. The lake receives drainage from Idaho and western Montana. The river flows in a westward course to join the Columbia River. The principal economic activities in this area are lumbering, wheat, fruit, livestock and mining and associated processing.

Pend Oreille River—This stream is headed by a lake and receives drainage from Washington, Idaho, western Montana, and Canada. It flows 119 miles west and northwestward to the Columbia River in Can The majority of the drainage basin is covered by natural forests.

Clearwater River—This stream which is tributary to the Snake R drains north central Idaho. A small portion of the drainage is tributed by western Washington. Much of the headwater area i natural forests and lumbering and lumber mills are the principal nomic activity. Some farming is also carried on.

Detailed descriptions of the individual Public Health Se Water Pollution Surveillance System stations, together with additi environmental information is presented with the analytical and flow

In general, runoff is high in this basin and mineral concentrat are fairly low except where the water has been used for irriga

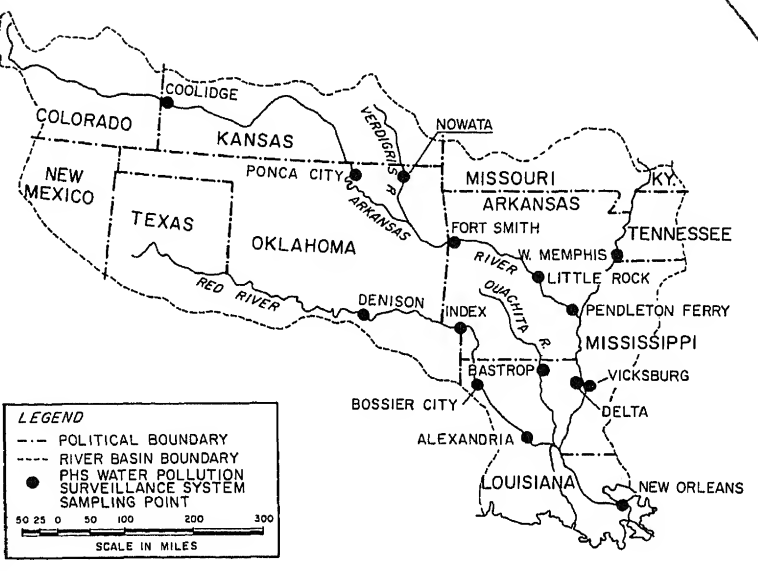
Phytoplankton counts at stations in this basin are generally than 5,000/milliliter, except at Payette, Idaho, on the Snake River w summer maxima exceed 40,000/milliliter. It is interesting to note Payette is the only station in the basin at which centric diatoms a wide margin of dominance. Summer pulses of coccoid green p lations contribute substantially to the higher phytoplankton count this station. Water hardness and the concentration of dissolved p phate are greater at this station than in the basin at large, and ma contributing environmental factors.

The phytoplankton of the basin consists largely of diatoms. more abundant pennate diatoms include *Asterionella formosa, F laria crotonensis, Tabellaria fenestrata, Diatoma spp.*, and *Synedra* Dominant centric diatoms include *Stephanodiscus hantzschii, Mel ambigua*, and *Melosira granulata*.

Rotifer populations of 500/liter occur on the lower Colum but the numbers decrease to low levels upstream and in tributa

BASIN 10

SOUTHWEST-LOWER MISSISSIPPI



The Southwest-Lower Mississippi River basin contains 15 Public Health Service Water Pollution Surveillance System stations situated on 5 rivers. Four stations are on the Mississippi River mainstem below the confluence of the Ohio River, five are on the Arkansas River mainstem, and four are on the mainstem of the Red River. The Verdigris and the Ouachita Rivers, tributary to the Arkansas and Red Rivers, respectively, are also sampled.

Arkansas River: The headwaters of the Arkansas River are in the Rocky Mountains near Leadville, Colo. The river flows in a southeasterly course to its confluence with the Mississippi River. Irrigation places heavy demands on the stream in the semiarid and dry regions east of the mountains. Dissolved solids build up as a result of both natural and man-made pollution above Tulsa, Okla., and are subsequently reduced by dilution from other streams in Arkansas. Pueblo, Colo., is the only large community to use the Arkansas River as a municipal supply. The Verdigris River drains from eastern Kansas southward through Oklahoma and is confluent with the Arkansas River near Muskogee, Okla.

Red River: The Red River begins in the high plains of Texas. South of Amarillo in Palo Duro Canyon, the stream is degraded by rising salty ground water from several natural sources in this basin. Oil field pollution is being rapidly corrected. The Red River is subsequently diluted by the Washita River which enters Lake Texoma above Denison Dam and thereafter by several large tributaries. However, the variability of rainfall, and the operation of Denison Dam cause fluctuating mineral concentrations in the lower portion of this river. One municipality uses the Red River as a source of supply. The Red River is confluent to the Atchafalaya River which is a distributary of the lower Mississippi.

Ouachita River: The Ouachita River flows southward from central Arkansas and, in its lower reach, becomes the Black River. The Black River is tributary to the Red River about 30 miles downstream from Alexandria, La.

The Surveillance System station at West Memphis, Ark., monitors inflow to the lower Mississippi River and the New Orleans station monitors the discharge of the Mississippi to the Gulf of Mexico. Twin stations are installed at Delta, La., and Vicksburg, Miss., in order to

densities, and average precipitation varies from about 40 inches annually in the valleys to 100 inches or more in the mountain areas. Temperatures vary from about 10° to 100° F. along the coast and from minus 50° to plus 120° F. in the inland areas.

Willamette River—This river rises in southwest Oregon and flows northward 300 miles to its confluence with the Columbia River at Portland. It is navigable to Eugene, 178 miles upstream. The Willamette drains the most heavily populated part of Oregon. Agriculture, food processing, and lumbering operations are the principal economic activities.

Snake River—This stream is the chief tributary to the Columbia River. It rises in Yellowstone National Park and flows for about 1,000 miles before joining the Columbia near Pasco, Wash. This stream has cut a canyon which reaches a depth of 5,500 feet. The major population centers of Idaho are located along this stream and both private and Federal irrigation projects are active.

Yakima River—This stream rises on the east slope of the Cascade Range and flows 203 miles to the Columbia. Extensive use is made of this stream for irrigation and hydroelectric power.

Spokane River—This river originates below Coeur d'Alene Lake in western Idaho. The lake receives drainage from Idaho and western Montana. The river flows in a westward course to join the Columbia River. The principal economic activities in this area are lumbering, wheat, fruit, livestock and mining and associated processing.

Pend Oreille River—This stream is headed by a lake and receives drainage from Washington, Idaho, western Montana, and Canada. It flows 119 miles west and northwestward to the Columbia River in The majority of the drainage basin is covered by natural forests

Clearwater River—This stream which is tributary to the Sna drains north central Idaho. A small portion of the drainag tributed by western Washington. Much of the headwater a natural forests and lumbering and lumber mills are the princ nomic activity. Some farming is also carried on.

CLEARWATER RIVER AT LEWISTON, IDAHO

The Clearwater River is monitored by the Water Pollution Surveillance System approximately two miles above its confluence with the Snake River at the municipal water plant intake. There are minor municipal discharges located at least 40 miles upstream from the station. The nearby area is rather hilly and stock raising is the principal agricultural activity. A Kraft pulp mill is located above the station and utilizes some 30 to 40 million gallons per day of water from the Clearwater River. Wastes from this plant are discharged to the confluence of the Snake and Clearwater Rivers below the Surveillance station. There is a log pond associated with this plant.

736-491 O—64——3

Station Location: Clearwater River At Lewiston, Idaho

Major Basin: Pacific Northwest

Minor Basin: Middle and Lower Snake River

Station at: 46°25' Latitude 116°58' Longitude

Miles above mouth: 2

Activation Date: October 9, 1961

Sampled by: Lewiston Water Department

Field Analysis by: Lewiston Water Department

Other Cooperating Agencies: Idaho Department of Health

Hydrologic Data:

Nearest pertinent gaging station: At Spalding, Idaho

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: 9,570 square miles

Period of record: 1910-1913, 1925 to present

Average discharge in record period: 15,250 cfs.

Maximum discharge in record period: 177,000 cfs.

Minimum discharge in record period: 500

Remarks: Small amount of diversion upstream. Flow affected by powerplants on upstream tributary.

COLUMBIA RIVER AT CLATSKANIE, OREGON

The Clatskanie station is the lower terminal Water Pollution Surveillance System station on the Columbia River, and monitors essentially the total outflow of the Columbia River drainage basin. Samples are collected at the wharf of Beaver Army Terminal, U. S. Army Transportation Supply and Maintenance Command.

The Cowlitz River and Willamette River are confluent to the Columbia in the reach upstream from Clatskanie and below the next mainstem monitoring station at Bonneville, Oregon. The nearest major upstream communities above this station are Portland, Oregon and Longview, Kelso, and Vancouver, Washington. These cities discharge a total BOD population equivalent of about 485,000 to either the mainstem or a tributary. Sewage treatment plant improvements now under construction will reduce this loading. Grains and timber are the principal crops grown in this reach, and pulp mills are the leading industrial activity, especially in the Kelso-Longview area.

Station Location: Columbia River At Clatskanie, Oregon

Major Basin: Pacific Northwest

Minor Basin: Columbia River below Yakima River

Station at: 46°10' Latitude 123°12' Longitude

Miles above mouth: 54

Activation Date: April 4, 1958

Sampled by: U.S. Army
U.S. Public Health Service

Field Analysis by: U.S. Public Health Service

Other Cooperating Agencies: Oregon State Sanitary Authority

Hydrologic Data:

Nearest pertinent gaging station: See Remarks

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: Estimated 259,000 square miles at sampling point.

Period of record: —

Average discharge in record period: Estimated 269,000 cfs. at sampling point

Maximum discharge in record period: —

Minimum discharge in record period: —

Remarks: Flow at Clatskanie computed as the sum of Columbia River near The Dalles plus 4 times the sum of Klickitat River near Pitt, Washington and Hood River and Conduit near Hood River, Oregon, plus Willamette River at Salem, Oregon plus 4.5 times the Cowlitz River at Castle Rock, Washington.

SPECIFIC QUALITATIVE IDENTIFICATIONS FROM CARBON ADSORPTION EXTRACTS WATER YEAR 1962-3

Interval	Compound	Concentration* ug/l

*Concentration values, where shown, are calculated from quantitative gas chromatographic analysis of the aromatic fractions of CCE, and may be assigned the units of ug/l. In light of the unknown efficiency of carbon adsorption sampling for these compounds, the reported values represent minima, the actual values being equal to or greater than the reported values.
See page 21.

Computed as sum of Columbia River near The Dalles, Oregon plus 4 times the sum of Klickitat River near Pitt, Washington and Hood River and Conduit near Hood River, Oregon, plus Willamette River at Salem, Oregon plus 4.5 times the Cowlitz River at Castle Rock, Washington.

COLUMBIA RIVER AT BONNEVILLE, OREGON

The Bonneville Water Pollution Surveillance System station is located in the Bonneville Dam Powerhouse. The Columbia River is navigable at this point and above. Occasional pollution has resulted from oil leaks in barges carrying petroleum products. Hood River and The Dalles, Oregon and White Salmon, Washington are the three major upstream communities. All are within 40 miles of the sampling point and discharge treated wastes to the mainstem. There are lumber mills at Cascade Locks and Stevenson, Washington, 4 miles upstream.

The Columbia River in this area is extensively used for power production and recreation.

Station Location: Columbia River At Bonneville, Oregon

Major Basin: Pacific Northwest

Minor Basin: Columbia River below Yakima River

Station at: 45°38' Latitude 121°57' Longitude

Miles above mouth: 146

Activation Date: November 11, 1957

Sampled by: U.S. Army Corps of Engineers

Field Analysis by: Crown Zellerbach Corporation

Other Cooperating Agencies: Oregon State Sanitary Authority

Hydrologic Data:

Nearest pertinent gaging station: See Remarks

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: Estimated 240,000 square miles at sampling point

Period of record: —

Average discharge in record period: Estimated 200,000 cfs. at sampling point

Maximum discharge in record period: —

Minimum discharge in record period: —

Remarks: Flow at Bonneville computed as the sum of Columbia River near The Dalles, Oregon plus twice the sum of Klickitat River near Pitt, Washington and Hood River and Conduit near Hood River, Oregon.

Computed as sum of Columbia River near The Dalles, Oregon plus twice the sum of Klickitat River near Pitt, Washington and Hood River and conduit near Hood River, Oregon.

COLUMBIA RIVER AT McNARY DAM, OREGON

The McNary Dam Surveillance System station is located in the McNary Dam powerhouse and monitors the outflow from McNary Reservoir.

There are no major communities on the Columbia River between McNary Dam and the next upstream surveillance station at Pasco, Washington. There is, however, a pulp mill in this reach. The principal economic activity in the area is wheat farming. A moderate amount of irrigation is practiced.

The Snake River is confluent to the Columbia in the McNary Dam-Pasco reach.

Station Location: Columbia River at McNary Dam, Oregon

Major Basin: Pacific Northwest

Minor Basin: Columbia River below Yakima River

Station at: 45°57' Latitude 119°18' Longitude

Miles above mouth: 292

Activation Date: April 1, 1961

Sampled by: U. S. Army Corps of Engineers
Washington State Pollution Control Commission

Field Analysis by: Public Health Service

Other Cooperating Agencies: Washington State Department of Health
U. S. Geological Survey

Hydrologic Data:

Nearest pertinent gaging station: below McNary Dam, Oregon

Gaging station operated by: U. S. Geological Survey

Drainage area at gaging station: 214,000 square miles

Period of record: 1950 to present

Average discharge in record period: 188,500 cfs.

Maximum discharge in record period: 818,000 cfs.

Minimum discharge in record period: 50,600 cfs.

Remarks: Irrigation diversions above station. Flow regulated somewhat by Roosevelt Lake and tributary reservoirs. Flow affected by McNary Dam power plant operation since April 1953.

SPECIFIC QUALITATIVE IDENTIFICATIONS FROM CARBON ADSORPTION EXTRACTS WATER YEAR 1962-3

Interval	Compound	Concentration* ug/l
11/5-11/19/62	DDT	

*Concentration values, where shown, are calculated from quantitative gas chromatographic analysis of the aromatic fractions of CCE, and may be assigned the units of ug/l. In light of the unknown efficiency of carbon adsorption sampling for these compounds, the reported values represent minima, the actual values being equal to or greater than the reported values.

See page 21.

COLUMBIA RIVER AT PASCO, WASHINGTON

The Water Pollution Surveillance System station is located above the mouth of the Snake River and below the mouth of the Yakima River. Samples are collected at the municipal water plant intake.

The Hanford Atomic Energy Works is located above this station and its industrial wastes, including reactor cooling waters, are discharged to the Columbia River. The communities of Richland, Pasco, and Kennewick, Washington with populations of approximately 23,500, 15,000 and 14,000 respectively (1960 census) utilize the Columbia River below the Hanford Atomic Works as a source of community water supply.

Richland, Washington discharges approximately 10,200 BOD population equivalents of treated wastes into the Yakima River near its confluence with the Columbia River. This confluence point is located approximately six miles upstream from the Pasco station.

Station Location: Columbia River At Pasco, Washington

Major Basin: Pacific Northwest

Minor Basin: Middle and Lower Snake River

Station at: 46°13' Latitude 119°06' Longitude

Miles above mouth: 329

Activation Date: November 4, 1957

Sampled by: Pasco Water Department

Field Analysis by: Pasco Water Department

Other Cooperating Agencies: Washington State Department of Health
Washington State Pollution Control Commission

Hydrologic Data:

Nearest pertinent gaging station: See Remarks

Gaging station operated by: U. S. Geological Survey

Drainage area at gaging station: Estimated 122,000 square miles at sampling point

Period of record: —

Average discharge in record period: 123,000 (estimated)

Maximum discharge in record period: —

Minimum discharge in record period: —

Remarks: Flow at Pasco computed as sum of Columbia River at Trinidad, Washington plus Yakima River at Kiona, Washington

ALKYL BENZENE SULFONATE (ABS)

Date	mg/l

ELEMENTAL ANALYSES

Analysis by wet or flame methods. Results in mg/l

Analysis by Spectrographic methods. Results in micrograms per liter

Computed as sum of Columbia River at Trinidad, Washington plus Yakima River at Kiona, Washington.

COLUMBIA RIVER AT WENATCHEE, WASHINGTON

This station is located at the plant intake of the Wenatchee Works of the Aluminum Company of America, some 70 miles upstream from the Hanford Atomic Works. Wenatchee and East Wenatchee discharge wastes with a total of about 13,000 BOD population equivalents to the Columbia River about 12 miles upstream. Other industries in the area include irrigated agriculture, ore smelting, and meat processing.

Grand Coulee Dam and Franklin D. Roosevelt Lake are about halfway between this station and the next Surveillance System station at Northport, Washington. The Spokane River is confluent to the Columbia in Franklin D. Roosevelt Lake.

736-491 O—64——6

Station Location: Columbia River At Wenatchee, Washington

Major Basin: Pacific Northwest

Minor Basin: Columbia River above Yakima River

Station at: 47°21' Latitude 120°07' Longitude

Miles above mouth: 458

Activation Date: October 6, 1958

Sampled by: Aluminum Company of America

Field Analysis by: Aluminum Company of America

Other Cooperating Agencies: Washington State Department of Health
Washington State Pollution Control Commission

Hydrologic Data:

Nearest pertinent gaging station: At Trinidad, Washington

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: 89,700 square miles

Period of record: 1913 to Present

Average discharge in record period: 120,400 cfs.

Maximum discharge in record period: 692,000 cfs.

Minimum discharge in record period: 4,120 cfs.

Remarks: Flow regulated by Rock Island, Rocky Reach, Grand Coulee, and St. Joseph Dams. Irrigation diversions above station for about 500,000 acres. Reservoirs on major tributaries.

ALKYL BENZENE SULFONATE (ABS)

Date	mg/l

Interval	Compound	Concentration* ug/l
10/11 - 12/62 (c)	DDT	

*Concentration values, where shown, are calculated from quantitative gas chromatographic analysis of the aromatic fractions of CCE, and may be assigned the units of ug/l. In light of the unknown efficiency of carbon adsorption sampling for these compounds, the reported values represent minima, the actual values being equal to or greater than the reported values.
See page 21.

COLUMBIA RIVER AT NORTHPORT, WASHINGTON

This is the upper terminal station in the Columbia River mainstem. The station is approximately 14 miles downstream from the Canadian border. The Pend Oreille River which rises in the United States and enters Canada is confluent to the Columbia above this station.

Samples other than organic chemicals are collected from Washington State Highway Number 22 bridge at Northport. The carbon adsorption unit is located approximately 3 miles downstream on the east bank of the river.

Station Location: Columbia River at Northport, Washington

Major Basin: Pacific Northwest

Minor Basin: Columbia River above Yakima River

Station at: 48°54' Latitude 117°50' Longitude

Miles above mouth: 734

Activation Date: May 14, 1962

Sampled by: Interested Citizens, by special arrangement

Field Analysis by: U.S. Public Health Service

Other Cooperating Agencies: Washington State Department of Health
Washington State Pollution Control Commission

Hydrologic Data:

Nearest pertinent gaging station: at International Boundary

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: 59,700 square miles

Period of record: 1937 to date

Average discharge in record period: 98,680 cfs.

Maximum discharge in record period: 550,100 cfs.

Minimum discharge in record period: 18,000 cfs.

Remarks: Diversion for irrigation of approximately 400,000 acres above gaging station. Flow regulated by lakes and reservoirs on mainstem and tributaries.

ALKYL BENZENE SULFONATE (ABS)

SPECIFIC QUALITATIVE IDENTIFICATIONS FROM CARBON ADSORPTION EXTRACTS WATER YEAR 1962-3

Interval	Compound	Concentration* ug/l
10/20 - 10/27/62	DDT	

*Concentration values, where shown, are calculated from quantitative gas chromatographic analysis of the aromatic fractions of CCE, and may be assigned the units of ug/l. In light of the unknown efficiency of carbon adsorption sampling for these compounds, the reported values represent minima, the actual values being equal to or greater than the reported values.

PEND OREILLE RIVER AT ALBENI FALLS DAM, IDAHO

This Water Pollution Surveillance System station is located in the Albeni Falls Dam powerhouse. Albeni Falls Dam, located near the Washington-Idaho border, creates an impoundment which extends upstream to Pend Oreille Lake, a large natural lake. The principal stream feeding Lake Pend Oreille is the Clark Fork River which drains a large portion of western Montana.

The principal community on Pend Oreille Lake is Sandpoint, Idaho which discharges an estimated 1300 BOD population equivalents of treated wastes into the Lake near its outlet to the Pend Oreille River. Priest River, Idaho discharges approximately 480 BOD population equivalents of treated municipal waste to Pend Oreille River above the Surveillance System station. No major municipal waste loads are discharged to the Pend Oreille River below the station.

Station Location: Pend Oreille River at Albeni Falls Dam, Idaho

Major Basin: Pacific Northwest

Minor Basin: Clark Fork-Pend Oreille River

Station at: 48°10' Latitude 117°00' Longitude

Miles above mouth: 90

Activation Date: May 14, 1962

Sampled by: U.S. Army Corps of Engineers

Field Analysis by: U.S. Public Health Service

Other Cooperating Agencies: Washington State Department of Health
Idaho State Board of Health

Hydrologic Data:

Nearest pertinent gaging station: At Newport Washington

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: 24,200 square miles

Period of record: 1903-1941, 1952 to present

Average discharge in record period: 25,410 cfs.

Maximum discharge in record period: 136,000 cfs.

Minimum discharge in record period: 1,280 cfs.

Remarks: Flow regulated by Albeni Falls Dam and influenced by upstream lakes and reservoirs. Diversions are made in the upper portion of the basin above the station for irrigation of approximately 340,000 acres.

SNAKE RIVER AT ICE HARBOR DAM, WASHINGTON

This Water Pollution Surveillance System station is located in the Ice Harbor Dam powerhouse and monitors the discharge of the Snake River to the Columbia River.

There are no municipal water users within 100 miles upstream of this station. The flow is regulated and provides for an extensive irrigated agriculture.

Station Location: Snake River at Ice Harbor Dam, Washington

Major Basin: Pacific Northwest

Minor Basin: Middle and Lower Snake River

Station at: 46°15' Latitude 118°53' Longitude

Miles above mouth: 10

Activation Date: May 21, 1962

Sampled by: U.S. Army Corps of Engineers

Field Analysis by: U.S. Public Health Service

Other Cooperating Agencies: Washington State Department of Health
Washington State Pollution Control Commission

Hydrologic Data:

Nearest pertinent gaging station: Near Clarkston, Washington

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: 103,200 square miles

Period of record: 1915 to present

Average discharge in record period: 45,140 cfs. W.Y. 1962

Maximum discharge in record period: 369,000 cfs.

Minimum discharge in record period: 6,660 cfs.

Remarks: Irrigation diversion for approximately 2.8 million acres above gaging station. Flow regulated by storage reservoirs and affected by powerplants.

ALKYL BENZENE SULFONATE (ABS)

SPECIFIC QUALITATIVE IDENTIFICATIONS FROM CARBON ADSORPTION EXTRACTS WATER YEAR 1962-3

Interval	Compound	Concentration* ug/l

*Concentration values, where shown, are calculated from quantitative gas chromatographic analysis of the aromatic fractions of CCE, and may be assigned the units of ug/l. In light of the unknown efficiency of carbon adsorption sampling for these compounds, the reported values represent minima, the actual values being equal to or greater than the reported values.
See page 21.

SNAKE RIVER AT WAWAWAI, WASHINGTON

This Pollution Surveillance System station is located at the pumping station of the I. E. Wilson Farm about 25 miles below the point where the Snake River turns westward and starts to flow entirely through Washington. Clarkston, Washington and Lewiston, Idaho are the two major communities 25 miles upstream that may influence water quality at this station. These cities contribute 7,800 BOD population equivalents through treated sewage. Pulp mill wastes are also discharged to the river in the Lewiston-Clarkston area.

Irrigation water is diverted from the stream principally in the southern Idaho portion of the drainage.

The Clearwater River is a tributary to the Snake River at Lewiston, Idaho.

Station Location: Snake River at Wawawai, Washington

Major Basin: Pacific Northwest

Minor Basin: Middle and Lower Snake River

Station at: 46°38' Latitude 117°23' Longitude

Miles above mouth: 111

Activation Date: August 4, 1958

Sampled by: Washington State University

Field Analysis by: Washington State University

Other Cooperating Agencies: Washington State Department of Health

Hydrologic Data:

Nearest pertinent gaging station: near Clarkston, Washington

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: 103,200 square miles

Period of record: 1915 to present

Average discharge in record period: 45,140 cfs. (for 1962 water year only)

Maximum discharge in record period: 369,000 cfs.

Minimum discharge in record period: 6,660 cfs.

Remarks: Diversion for irrigation of more than 2.8 million acres above gaging station. Regulated by upstream storage reservoirs and affected by power plant operation.

ALKYL BENZENE SULFONATE (ABS)

Date	mg/l

SPECIFIC QUALITATIVE IDENTIFICATIONS FROM CARBON ADSORPTION EXTRACTS WATER YEAR 1962-3

Interval	Compound	Concentration* ug/l

*Concentration values, where shown, are calculated from quantitative gas chromatographic analysis of the aromatic fractions of CCE, and may be assigned the units of ug/l. In light of the unknown efficiency of carbon adsorption sampling for these compounds, the reported values represent minima, the actual values being equal to or greater than the reported values.

The Payette station of the Water Pollution Surveillance System is located at the highway bridge crossing the Snake River. It is the uppermost station along the Snake River and is located in the reach of the river forming the Oregon-Idaho border. Municipal wastes with a total BOD population equivalent of approximately 13,000 are discharged to the Snake River within 4 miles upstream of the station.

Upstream from the station, about 2.5 million acres are under irrigation with sugar beets, potatoes, and grains being the principal crops. Wastes from food processing plants associated with these crops enter the Snake River and its tributaries above the Payette station.

Station Location: Snake River at Payette, Idaho

Major Basin: Pacific Northwest

Minor Basin: Central Snake River

Station at: 44°06' Latitude 116°56' Longitude

Miles above mouth: 366

Activation Date: October 2, 1961

Sampled by: Payette Water Department

Field Analysis by: Idaho State Department of Health

Other Cooperating Agencies: None

Hydrologic Data:

Nearest pertinent gaging station: at Weiser, Idaho

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: 69,200 square miles

Period of record: 1910 to present

Average discharge in record period: 13,600 cfs. (1962 water year only)

Maximum discharge in record period: 84,500 cfs.

Minimum discharge in record period: 5,100 cfs.

Remarks: Diversion for irrigation of approximately 2.5 million acres above station. Flow affected by upstream power plant and regulated by reservoirs.

ALKYL BENZENE SULFONATE (ABS)

Date	mg/l

SPECIFIC QUALITATIVE IDENTIFICATION FROM CARBON ADSORPTION EXTRACTS WATER YEAR 1962-3

Interval	Compound	Concentration* ug/l

*Concentration values, where shown, are calculated from quantitative gas chromatographic analysis of the aromatic fractions of CCE, and may be assigned the units of ug/l. In light of the unknown efficiency of carbon adsorption sampling for these compounds, the reported values represent minima, the actual values being equal to or greater than the reported values.

See page 21.

SPOKANE RIVER AT POST FALLS DAM, IDAHO

This station is located in the Post Falls Dam powerhouse two miles upstream from the Washington-Idaho State line and seven miles downstream from Coeur d'Alene, Idaho. This city draws its municipal water supply from Coeur d'Alene Lake and returns its treated sewage, having a BOD population equivalent of 1500 to the river above the sampling station. Lumbering is the principal industry in this area.

The lower reach of the Spokane River is in pool above Grand Coulee Dam after flowing through Spokane, Washington.

Station Location: Spokane River at Post Falls Dam, Idaho

Major Basin: Pacific Northwest

Minor Basin: Spokane River

Station at: 47°42' Latitude 116°58' Longitude

Miles above mouth: 98

Activation Date: May 14, 1962

Sampled by: Washington Water Power Company

Field Analysis by: U.S. Public Health Service

Other Cooperating Agencies: Washington State Department of Health
Idaho State Department of Health

Hydrologic Data:

Nearest pertinent gaging station: Near Post Falls, Idaho

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: 3,840 square miles of which 122 are non-contributing

Period of record: 1912 to present

Average discharge in record period: 6,224 cfs. river only

Maximum discharge in record period: 50,100 cfs.

Minimum discharge in record period: 104 cfs.

Remarks: Some irrigation diversion around station. Flow regulated by Post Falls Dam and influenced by Coeur d'Alene Lake.

ALKYL BENZENE SULFONATE (ABS)

Date	mg/l

Interval	Compound	Concentration* ug/l

*Concentration values, where shown, are calculated from quantitative gas chromatographic analysis of the aromatic fractions of CCE, and may be assigned the units of ug/l. In light of the unknown efficiency of carbon adsorption sampling for these compounds, the reported values represent minima, the actual values being equal to or greater than the reported values.
See page 21.

This station is located at Swan Island 8 1/2 miles above the confluence of the Willamette River and Columbia River. It is estimated that wastes with a BOD population equivalent of some 180,000 enter the Portland Harbor reach of the Willamette River on which the Surveillance station is located. Two pulp mills are located at Oregon City approximately 18 miles above the station. The largest upstream municipality contributing waste is Salem, Oregon which during the canning season discharges some 250,000 BOD population equivalents to the Willamette River and at other times a load of approximately 70,000 BOD population equivalents. Waste treatment facilities are being expanded and improved at Salem.

Station Location:	Willamette River at Portland, Oregon
Major Basin:	Pacific Northwest
Minor Basin:	Willamette River
Station at:	45°33' Latitude 122°43' Longitude
Miles above mouth:	8.5
Activation Date:	August 13, 1962
Sampled by:	U.S. Public Health Service
Field Analysis by:	U.S. Public Health Service
Other Cooperating Agencies:	Oregon State Sanitary Authority
Hydrologic Data:	
Nearest pertinent gaging station:	At Salem, Oregon
Gaging station operated by:	U.S. Geological Survey
Drainage area at gaging station:	7,280 square miles
Period of record:	1909-1916, 1923 to present
Average discharge in record period:	23,360 cfs.

Maximum discharge in record period: 348,000 cfs.

Minimum discharge in record period: 2,470 cfs.

Remarks: Irrigation diversions above station. Many reservoirs regulate flow; most recent added in 1961, Hills Creek Reservoir. Other reservoirs operational before start of pollution surveillance activities.

6/5 - 6/13/63	α-conidendrin	
11/7 -11/18/63	α-conidendrin	

*Concentration values, where shown, are calculated from quantitative gas chromatographic analysis of the aromatic fractions of CCE, and may be assigned the units of ug/l. In light of the unknown efficiency of carbon adsorption sampling for these compounds, the reported values represent minima, the actual values being equal to or greater than the reported values.

See page 21.

YAKIMA RIVER AT RICHLAND, WASHINGTON

This Water Pollution Surveillance System station is located at the City pumping station near the terminus of the Yakima River basin. Extensive irrigation in the basin supports an agricultural economy which produces such diversified crops as: fruits; including apples, cherries, pears, etc.; hay and grain crops; vegetables; and such other crops as sugar beets, potatoes, and hops. Over one quarter million acres are irrigated in the Yakima basin. Yakima, the principal upstream community is located some 90 miles above the Surveillance station and discharges approximately 30,800 BOD population equivalents of treated wastes to the Yakima River. Food processing plants, lumber yards, and some manufacturing plants are located in and near the City of Yakima. Food processing plants which operate seasonally generate large quantities of industrial wastes. These wastes are extensively treated by lagooning and by sprinkler application to land areas. During the irrigation season a high percentage of the flow passing the Surveillance station at Richland consists of irrigation return drainage.

Station Location: Yakima River at Richland, Washington

Major Basin: Pacific Northwest

Minor Basin: Yakima River

Station at: 46°16' Latitude 119°18' Longitude

Miles above mouth: 5

Activation Date: March 29, 1961

Sampled by: City of Richland, Washington

Field Analysis by: Richland Water Department

Other Cooperating Agencies: Washington State Board of Health
Washington Pollution Control Commission

Hydrologic Data:

Nearest pertinent gaging station: at Kiona, Washington

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: 5,600 square miles

Period of record: 1896-1915, 1933 to present

Average discharge in record period: 2,752 cfs. 1962 W.Y. only

Maximum discharge in record period: 67,000 cfs.

Minimum discharge in record period: 105 cfs.

Remarks: Diversion for irrigation of approximately 450,000 acres above gaging station. Some irrigation diversion bypasses station. Some regulation by upstream lakes.

ALKYL BENZENE SULFONATE (ABS)

*Concentration values, where shown, are calculated from quantitative gas chromatographic analysis of the aromatic fractions of CCE, and may be assigned the units of ug/l. In light of the unknown efficiency of carbon adsorption sampling for these compounds, the reported values represent minima, the actual values being equal to or greater than the reported values.

ALASKA

Alaska embraces over 586,000 square miles with three climatic and hydrologic regions.

The southeastern (panhandle) and southern coastal region has a marine climate with mean temperatures at Ketchikan and Anchorage of 33° and 11° F. in January and 58° and 57° F. in July, respectively. Corresponding precipitation values are 151 inches and 14 inches per year. The Public Health Service Water Pollution Surveillance System station at Anchorage provides data on water quality in the northerly portion of this region.

The interior region is bounded on the south by the Alaska Range with a maximum elevation of 20,300 feet at Mount McKinley and on the north by the Brooks Range with elevations to 8,000 feet. Over 300,000 square miles of the interior drains into the Yukon River which begins within 25 miles of tidewater in southeastern Alaska and runs 2,300 miles to the Bering Sea. The Tanana River is a major tributary to the Yukon. The surveillance station at Fairbanks provides data on a tributary of the Tanana. Mean January and July temperatures at Fairbanks vary from about −12° and 60° F. Annual precipitation is about 12 inches.

The western and northern region includes the Aleutian Islands, the Bering Sea coast, and the Arctic drainage basins. Mean winter and summer temperatures vary from 32° and −17° F. to 51° and 40° F. at Dutch Harbor and Point Barrow, respectively. Corresponding precipitation totals about 57 and 4 inches annually.

CHENA RIVER AT FAIRBANKS, ALASKA

The Public Health Service Water Pollution Surveillance System station at Fairbanks is located at Fort Wainwright on the Chena River some 16 miles above the confluence of the Chena and Tanana Rivers. The Chena River at the sampling point is occasionally referred to as Chena Slough. Municipal and industrial wastes associated with the City of Fairbanks are discharged to the Chena River downstream from the Water Pollution Surveillance System station.

Station Location: Chena River at Fairbanks, Alaska

Major Basin: Alaska

Minor Basin: Yukon River

Station at: 64°51' Latitude 147°36' Longitude

Miles above mouth: 16

Activation Date: June 4, 1962

Sampled by: Fairbanks Municipal Utilities System

Field Analysis by: Fairbanks Municipal Utilities System

Other Cooperating Agencies: Alaska State Department of Health and Welfare
U.S. Army

Hydrologic Data:

Nearest pertinent gaging station: Fairbanks, Alaska

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: 1,980 square miles

Period of record: 1947 to date

Average discharge in record period: 1,464 cfs.

Maximum discharge in record period: 24,200 cfs.

Minimum discharge in record period: not determined

Remarks:

ALKYL BENZENE SULFONATE (ABS)

Date	mg/l

SHIP CREEK AT ANCHORAGE, ALASKA

The Anchorage Surveillance System station is located in the Anchorage water treatment plant and obtains samples from Ship Creek Reservoir. This stream is the municipal supply for Ft. Richardson and Elmendorf Air Force Base, and is part of the supply for Anchorage. The average diversion for this municipal use is 16 cubic feet per second.

Station Location: Ship Creek at Anchorage, Alaska

Major Basin: Alaska

Minor Basin: North Pacific Ocean

Station at: 61°13' Latitude 149°38' Longitude

Miles above mouth: 8

Activation Date: June 4, 1962

Sampled by: Greater Anchorage Health District

Field Analysis by: U.S. Public Health Service

Other Cooperating Agencies: Alaska Department of Health and Welfare

Hydrologic Data:

Nearest pertinent gaging station: near Anchorage, Alaska

Gaging station operated by: U.S. Geological Survey

Drainage area at gaging station: 91 square miles

Period of record: 1946 to present

Average discharge in record period: 162 cfs. W.Y. 1962 only

Maximum discharge in record period: 1,860 cfs.

Minimum discharge in record period: 0

Remarks: Municipal diversion of approximately 16 cfs. for Fort Richardson, Elmendorf Air Force Base and City of Anchorage above gaging station.
